Abstract: In this paper, we introduce the concept of Golden quaternion and then show that we cannot have golden quaternions, golden dual quaternions and golden hyperbolic quaternions. But; we show that we have golden biquaternions and investigate its basic properties. Furthermore, we obtain the Golden split quaternions, Golden dual split quaternions and Golden hyperbolic split quaternions by using the Lorentz metric, respectively and investigate their basic properties.

AMS Subject Classification: 11R52, 53B30, 15A33
Key Words: Golden ratio, quaternions, biquaternions, Lorentzian space, split quaternions, dual split quaternions

1. Introduction

The Golden ratio is an irrational number defined to be \( \frac{1 + \sqrt{5}}{2} \) which is the real positive root of the equation \( x^2 - x - 1 = 0 \). It has been of interest to mathematicians, physicists, philosophers, architects, artists and even musicians since antiquity. It has been called the Golden mean, the Golden section, the divine proportion, the Fibonacci number and the mean of Phidias. It has a value of 1.61803... and is denoted \( \phi \), from the first letter of the name of the mathematician Phidias. We say that a line-segment is divided in the ratio of the Golden section, or in the Golden
ratio, if the larger subsegment is related to the smaller exactly as the whole segment is related to the larger segment [15].

The Golden ratio is a popular ratio since the time of Euclid and we encounter it in many fields; for example, in dimensions of the human body, in the structure of musical compositions, and in the ratios of harmonious sound frequencies [12]. Furthermore, it plays an important role in architecture and visual arts. The Golden proportion and the Golden rectangle (which is spanned by two sides in the Golden proportion) have been found in the harmonious proportions of temples, churches, statues, paintings, pictures and fractals [5, 7].

The golden ratio is also used in the analysis of financial markets, in strategies such as Fibonacci retracement. In recent years, it has played an important role in differential geometry. M. Crasmareanu and C.E. Hretcanu [2] defined the Golden structure with the structure polynomial \( Q(x) = x^2 - x - I \) on a differentiable manifold and hence introduced the Golden ratio in differential geometry, which gives rise to the Golden differential geometry. Furthermore, E. Suresh defined Golden biquaternions, which also gives rise to the quaternion theory [3]. Our work is also based on E. Suresh’s study.

We can summarize this study as follows, briefly. First, we recall some basic concepts related to quaternions, biquaternions (complexified quaternions), split quaternions, dual split quaternions and hyperbolic split quaternions, respectively, in Section 2. In the next section, we introduce the concept of Golden quaternion, we investigate its basic properties, and present some examples. Moreover, we obtain split quaternions by using the Lorentz metric in quaternions. The split quaternion product is different from quaternion product since the metric is different. Hence, we separately investigate split quaternions as the golden quaternions.

2. Preliminaries

In this section, to make the paper self-contained, we list some basic concepts and notations related to quaternions, biquaternions (complex quaternions), split quaternions, dual split quaternions and hyperbolic split quaternions, respectively.

A quaternion algebra \( \mathbb{H} \) is an associative, non-commutative division ring with four basic elements \( \{1, e_1, e_2, e_3\} \) satisfying the equalities

\[
\begin{align*}
e_1^2 &= e_2^2 = e_3^2 = -1, \\
e_1 e_2 &= -e_2 e_1 = e_3, \\
e_2 e_3 &= -e_3 e_2 = e_1,
\end{align*}
\]
We write any quaternion in the form $q = q_0 + q_1e_1 + q_2e_2 + q_3e_3$ or $q = q = S_q + \overrightarrow{V}_q$ where the symbols $S_q = q_0$ and $\overrightarrow{V}_q = q_1e_1 + q_2e_2 + q_3e_3$ denote the scalar and vector parts of $q$. If $S_q = 0$ then $q$ is called a pure quaternion. The conjugate of the quaternion $q$ is denoted by $K_q$, and defined as $K_q = S_q - \overrightarrow{V}_q$. The norm of a quaternion $q$ is defined by

$$
\sqrt{qK_q} = \sqrt{K_qq} = \sqrt{q_0^2 + q_1^2 + q_2^2 + q_3^2}
$$

and denoted by $N_q$ and we say that $q_0 = \frac{N_q}{q}$ is a unit quaternion where $q \neq 0$. Every unit quaternion can be written in the form $q_0 = \cos \theta + \overrightarrow{S}_0 \sin \theta$ where $\overrightarrow{S}_0$ is a unit vector satisfying the equality $\overrightarrow{S}_0^2 = \overrightarrow{S}_0 \overrightarrow{S}_0 = -1$ and is called axis of the quaternion [10]. The quaternion product of two quaternions $p = p_0 + p_1e_1 + p_2e_2 + p_3e_3$ and $q = q_0 + q_1e_1 + q_2e_2 + q_3e_3$ is defined as

$$
pq = S_qS_p - \langle \overrightarrow{V}_p, \overrightarrow{V}_q \rangle + S_q\overrightarrow{V}_p + S_p\overrightarrow{V}_q + \overrightarrow{V}_p \wedge \overrightarrow{V}_q,
$$

where $\langle , \rangle$ and $\wedge$ are Euclidean inner product and vector product, respectively [6].

### 2.1. Complexified Quaternions

Let $1, e_1, e_2, e_3$ be the quaternion basis elements and $z_0, z_1, z_2, z_3 \in \mathbb{C}$. Then

$$
q = z_0 + z_1e_1 + z_2e_2 + z_3e_3
$$

is said to be a biquaternion (complexified quaternion). As a consequence of this definition, a biquaternion $q$ can also be written as

$$
q = q' + iq''
$$

where $q' = a_0 + a_1e_1 + a_2e_2 + a_3e_3$ and $q'' = a_0^* + a_1^*e_1 + a_2^*e_2 + a_3^*e_3$ are real and imaginary biquaternion components, respectively. Scalar and vector parts of biquaternion $q$ are denoted by $S_q = z_0$ and $\overrightarrow{V}_q = z_1e_1 + z_2e_2 + z_3e_3$, respectively. The complex numbers $z_0, z_1, z_2, z_3$ commute with the quaternion basis elements $1, e_1, e_2, e_3$. The quaternion algebra $\mathbb{H}$ is a normed division algebra. The algebra of complexified quaternion $\mathbb{P} = \mathbb{H} \otimes \mathbb{C}$ is not a division algebra since the norm can be zero. The norm of biquaternion $q = z_0 + z_1e_1 + z_2e_2 + z_3e_3$ is defined as $N_q = \sqrt{z_0^2 + z_1^2 + z_2^2 + z_3^2}$ and we say that $q_0 = \frac{q}{N_q}$ is a unit biquaternion where $N_q \neq 0$. 

$$
e_3e_1 = -e_1e_3 = e_2.
$$
2.2. Split Quaternions

First we recall some basic notions from Lorentzian geometry. The Minkowski 3–space $E_3^1$ is the Euclidean space endowed with the metric

$$g(\mathbf{u}, \mathbf{v}) = -u_1v_1 + u_2v_2 + u_3v_3,$$

where $\mathbf{u} = (u_1, u_2, u_3), \mathbf{v} = (v_1, v_2, v_3) \in E^3$. Since $g$ is an indefinite metric, a vector $\mathbf{u}$ in $E_3^1$ may have one of the three casual characters, i.e., it is spacelike if $g(\mathbf{u}, \mathbf{u}) > 0$ or $\mathbf{u} = 0$, timelike if $g(\mathbf{u}, \mathbf{u}) < 0$ and null (light-like) if $g(\mathbf{u}, \mathbf{u}) = 0$ and $\mathbf{u} \neq 0$ [9]. In [13], the Lorentzian vector product $\mathbf{u} \wedge_L \mathbf{v}$ of $\mathbf{u}$ and $\mathbf{v}$ is defined as

$$\mathbf{u} \wedge_L \mathbf{v} = \begin{vmatrix} -e_1 & e_2 & e_3 \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}.$$

The semi-Euclidean 4–space with 2–index is denoted $E_2^4$. The inner product of this semi-Euclidean space is given by

$$\langle \mathbf{u}, \mathbf{v} \rangle_{E_2^4} = -u_1v_1 - u_2v_2 + u_3v_3 + u_4v_4,$$

and we say that $\mathbf{u}$ is timelike, spacelike or lightlike if $\langle \mathbf{u}, \mathbf{u} \rangle_{E_2^4} < 0$, $\langle \mathbf{u}, \mathbf{u} \rangle_{E_2^4} > 0$ and $\langle \mathbf{u}, \mathbf{u} \rangle_{E_2^4} = 0$, respectively for the vector $\mathbf{u}$ in $E_2^4$. Split quaternions $\mathbb{H}$ are identified with the semi-Euclidean space $E_2^4$. Besides, the subspace of $\mathbb{H}$ consisting of pure split quaternions $\mathbb{H}_0$ is defined with the Minkowski 3–space [8].

A split quaternion algebra is an associative, non-commutative non-division ring with four basic elements $\{1, e_1, e_2, e_3\}$ satisfying the equalities

$$e_1^2 = -1, \quad e_2^2 = e_3^2 = 1,$$
$$e_1e_2 = -e_2e_1 = e_3, \quad e_2e_3 = -e_3e_2 = -e_1, \quad e_3e_1 = -e_1e_3 = e_2.$$

The split quaternion algebra is the even subalgebra of the Clifford algebra of 3-dimensional Lorentzian space. Scalar and vector parts of split quaternion $q$ are denoted by $S_q = q_0$ and $V_q = q_1e_1 + q_2e_2 + q_3e_3$, respectively. The split quaternion product of two split quaternions $p = p_0 + p_1e_1 + p_2e_2 + p_3e_3$ and $q = q_0 + q_1e_1 + q_2e_2 + q_3e_3$ is defined as

$$pq = S_pS_q + g(V_p, \overline{V_q}) + S_qV_p + S_p\overline{V_q} + V_p \wedge_L \overline{V_q}.$$
where \( g(,) \) and \( \langle , \rangle \) are Lorentzian inner product and vector product, respectively. If \( S_q = 0 \) then \( q \) is called pure split quaternion. Let \( q = q_0 + q_1 e_1 + q_2 e_2 + q_3 e_3 = S_q + V_q \) be a split quaternion. The conjugate of a split quaternion, denoted \( K_q \), is defined as \( K_q = S_q - V_q \). Since the vector parts of \( q \) and \( K_q \) differ only in sign, we have \( I_q \stackrel{\text{def}}{=} qK_q = K_q q \). We say that a split quaternion \( q \) is spacelike, timelike or lightlike if \( I_q < 0 \), \( I_q > 0 \), or \( I_q = 0 \), respectively. Obviously, \( -I_q = -q_0^2 - q_1^2 + q_2^2 + q_3^2 \) is identified with \( \langle q, q \rangle E_3^2 \) for the split quaternion \( q \). The norm of \( q = q_0 + q_1 e_1 + q_2 e_2 + q_3 e_3 \) is defined as \( N_q = \sqrt{q_0^2 + q_1^2 - q_2^2 - q_3^2} \). If \( N_q = 1 \) then \( q \) is called the unit split quaternion and \( q_0 = \frac{1}{N_q} \) is a unit split quaternion for \( N_q \neq 0 \). Also, spacelike and timelike quaternions have multiplicative inverses and they satisfy the property \( qq^{-1} = q^{-1}q = 1 \). They are constructed as \( q^{-1} = \frac{K_q}{I_q} \). Lightlike quaternions have no inverses [14].

Vector part of any spacelike quaternion is spacelike since \( q_0^2 + q_1^2 - q_2^2 - q_3^2 < 0 \) and \( 0 < q_0^2 < -q_1^2 + q_2^2 + q_3^2 = g(V_q, V_q) \). But, vector part of any timelike quaternion can be spacelike, timelike or null in \( E_3^2 \). This is important especially for polar forms and rotations [14].

i) Every spacelike quaternion can be written in the form
\[
q = N_q (\sinh \theta + \bar{S}_0 \cosh \theta)
\]
where \( \sinh \theta = \frac{q_0}{N_q} \) and \( \cosh \theta = \frac{\sqrt{q_0^2 + q_1^2 - q_2^2 - q_3^2}}{N_q} \) is a spacelike unit vector in \( E_3^2 \) and \( \bar{S}_0^2 = 1 \).

ii) Every timelike quaternion with spacelike vector part can be written in the form
\[
q = N_q (\cosh \theta + \bar{S}_0 \sinh \theta)
\]
where \( \cosh \theta = \frac{q_0}{N_q} \) and \( \sinh \theta = \frac{\sqrt{q_0^2 + q_1^2 - q_2^2 - q_3^2}}{N_q} \) is a spacelike unit vector in \( E_3^2 \) and \( \bar{S}_0^2 = 1 \).

iii) Every timelike quaternion with timelike vector part can be written in the form
\[
q = N_q (\cos \theta + \bar{S}_0 \sin \theta)
\]
where \( \cos \theta = \frac{q_0}{N_q} \), \( \sin \theta = \frac{\sqrt{q_0^2 - q_1^2 + q_2^2 + q_3^2}}{N_q} \) and \( \bar{S}_0^2 = \frac{q_1 e_1 + q_2 e_2 + q_3 e_3}{\sqrt{q_1^2 - q_2^2 - q_3^2}} \) is a timelike unit vector in \( E_3^2 \) and \( \bar{S}_0^2 = -1 \).

2.3. Dual Numbers and Dual Split Quaternions

After we give a brief summary of dual numbers, we recall dual split quaternions.
Each element of the set

\[ D = \{ A = a + \varepsilon a^* | a, a^* \in \mathbb{R} \text{ and } \varepsilon \neq 0, \varepsilon^2 = 0 \} \]

is called a dual number. A dual number \( A = a + \varepsilon a^* \) can be expressed in the form

\[ A = ReA + \varepsilon DuA, \]

where \( ReA = a \) and \( DuA = a^* \).

Addition and multiplication of two dual numbers \( A = a + \varepsilon a^* \) and \( B = b + \varepsilon b^* \) are defined as

\[ A + B = (a + b) + \varepsilon(a^* + b^*), \]
\[ AB = ab + \varepsilon(ab^* + a^*b) \]

respectively and the conjugate of \( A = a + \varepsilon a^* \) is defined as \( \overline{A} = a - \varepsilon a^* \) [6].

A dual split quaternion \( Q \) is defined by

\[ Q = A_0 + A_1e_1 + A_2e_2 + A_3e_3 \]

where \( A_0, A_1, A_2, A_3 \in \mathbb{D} \). As a consequence of this definition, a dual split quaternion \( Q \) can also be written as

\[ Q = q + \varepsilon q^* \]

where \( q = a_0 + a_1e_1 + a_2e_2 + a_3e_3 \) and \( q^* = a_0^* + a_1^*e_1 + a_2^*e_2 + a_3^*e_3 \) are real and dual split quaternion components, respectively. Scalar and vector parts of dual split quaternion \( Q \) are denoted by \( S_Q = A_0 \) and \( V_Q = A_1e_1 + A_2e_2 + A_3e_3 \), respectively. The Hamilton conjugate of \( Q \), denoted \( K_Q \), is defined as \( K_Q = S_Q - V_Q = 7 + \varepsilon q^* \). The norm of a dual split quaternion \( Q \) is defined by \( \sqrt{QK_Q} = \sqrt{K_QQ} = \sqrt{A_0^2 + A_1^2 + A_2^2 + A_3^2} \) and denoted by \( N_Q \). For dual split quaternions with non-zero norm, the inverse is defined as \( Q^{-1} = \frac{K_Q}{N_Q^2} \) [11].

### 2.4. Hyperbolic Numbers and Hyperbolic Split Quaternions

In this last section, we give a brief summary of hyperbolic numbers and hyperbolic split quaternions.

Consider numbers of the form

\[ w = x + jy, \]

where \( x \) and \( y \) are real numbers, and \( j \) is a commuting element satisfying the relation

\[ j^2 = 1. \]
Such a number system is known as the hyperbolic number system. Addition and multiplication of two hyperbolic numbers $z = x_1 + jy_1$ and $w = x_2 + jy_2$ are, defined as

\[ z + w = (x_1 + x_2) + j(y_1 + y_2), \]
\[ zw = (x_1x_2 + y_1y_2) + j(x_1y_2 + x_2y_1). \]

Moreover, given any hyperbolic number $w = x + jy$, we define the conjugate of $w$, denoted $\overline{w}$, to be

\[ \overline{w} = x - jy. \]

(See [1]).

Let $1, e_1, e_2, e_3$ be the split quaternion basis elements and $Q_0, Q_1, Q_2, Q_3 \in H$. Then the expression

\[ q = Q_0 + Q_1e_1 + Q_2e_2 + Q_3e_3 \]

is a hyperbolic split quaternion. As a consequence of this definition, a hyperbolic split quaternion $Q$ can also be written as

\[ Q = Q' + jQ'' \]

where $Q' = Q_0' + Q_1'e_1 + Q_2'e_2 + Q_3'e_3$ and $Q'' = Q_0'' + Q_1''e_1 + Q_2''e_2 + Q_3''e_3$ are real and hyperbolic split quaternion components, respectively. Scalar and vector parts of hyperbolic split quaternion $Q$ are denoted by $S_Q = Q_0$ and $V_Q = Q_1e_1 + Q_2e_2 + Q_3e_3$, respectively. The conjugate of $Q$, denoted $K_Q$, is defined as $K_Q = S_Q - V_Q$.

The norm of a hyperbolic split quaternion $Q$ is defined by $\sqrt{K_Q\overline{K_Q}} = \sqrt{K_Q^2} = \sqrt{Q_0^2 + Q_1'^2 - Q_2'^2 - Q_3'^2}$ and denoted by $N_Q$. For hyperbolic split quaternions with non-zero norm, the inverse is defined as $Q^{-1} = \frac{K_Q}{N_Q}$.

### 3. Golden Quaternions

In this section, first we introduce the concept of the golden quaternion and then show that we cannot have golden, golden dual and golden hyperbolic quaternions. Next, we investigate golden biquaternions and present some examples. Finally, we introduce the concept of the golden split quaternion, golden dual split quaternions and golden hyperbolic split quaternion, respectively. Next, we investigate these quaternions and present some examples.
**Definition 3.1.** Let $Q$ be a quaternion if $Q$ satisfy the equation

$$Q^2 = Q + 1,$$

then we say that $Q$ is a golden quaternion.

Now, let $Q = S_Q + \vec{V}_Q$, then we have

$$Q^2 = S_Q^2 - \langle \vec{V}_Q, \vec{V}_Q \rangle + 2S_Q \vec{V}_Q.$$

In this case, the equation $Q^2 - Q = 1$ is equivalent to

$$S_Q^2 - \langle \vec{V}_Q, \vec{V}_Q \rangle + 2S_Q \vec{V}_Q - S_Q - \vec{V}_Q,$$

and we get

$$\begin{cases} S_Q^2 - \langle \vec{V}_Q, \vec{V}_Q \rangle - S_Q = 1 \\ 2S_Q \vec{V}_Q - \vec{V}_Q = 0. \end{cases}$$

(1)

Hence we get

$$S_Q = \frac{1}{2} \text{ or } \vec{V}_Q = 0.$$

Then there are two cases for golden quaternions:

1) $\vec{V}_Q = 0 \Rightarrow Q = \frac{1 \pm \sqrt{5}}{2}$,

2) $\vec{V}_Q \neq 0 \Rightarrow S_Q = \frac{1}{2} \text{ and } \langle \vec{V}_Q, \vec{V}_Q \rangle = -\frac{5}{4}$

Hence, we can say that there aren’t golden quaternions. Furthermore, we cannot have golden dual or golden hyperbolic quaternions.

**3.1. Golden Biquaternions**

But, we can have the golden biquaternions. Now, we try to explain the golden biquaternion. According to (2) we have

$$S_Q = \frac{1}{2} \text{ and } \langle \vec{V}_Q, \vec{V}_Q \rangle = -\frac{5}{4}.$$

Now, let $Q$ be a golden biquaternion, namely, $Q = z_0 + z_1 e_1 + z_2 e_2 + z_3 e_3$, where $z_i \in \mathbb{C}, i = 0, 1, 2, 3$. Then we have

$$z_0 = \frac{1}{2} \text{ and } z_1^2 + z_2^2 + z_3^2 = -\frac{5}{4}.$$

(3)
Thus we have

\[ N_Q = z_0^2 + z_1^2 + z_2^2 + z_3^2 = -1. \]  \tag{4}

We know that a unitary biquaternion is expressed as

\[ Q_0 = \frac{Q}{\sqrt{N_Q}} = \frac{z_0 + z_1e_1 + z_2e_2 + z_3e_3}{\sqrt{z_0^2 + z_1^2 + z_2^2 + z_3^2}}, \quad N_Q \neq 0. \]

If we consider

\[
\cos \theta = \frac{z_0}{\sqrt{N_Q}}, \quad \sin \theta = \frac{\sqrt{z_1^2 + z_2^2 + z_3^2}}{\sqrt{N_Q}} \quad \text{and} \quad \overrightarrow{S_0} = \frac{z_1e_1 + z_2e_2 + z_3e_3}{\sqrt{z_1^2 + z_2^2 + z_3^2}},
\]

then we can write a unitary biquaternion as

\[ Q_0 = \cos \theta + \overrightarrow{S_0} \sin \theta, \quad \theta \in C. \]  \tag{6}

Then, according to the equalities (3), (4), (5) and (6), a unitary golden biquaternion is in the form as follows:

\[ Q_0 = \frac{1}{2} + \frac{\sqrt{5}}{2} \overrightarrow{S_0}, \quad \langle \overrightarrow{S_0}, \overrightarrow{S_0} \rangle = 1, \quad \overrightarrow{S_0}^2 = -1, \]  \tag{7}

and since \( Q = Q_0 \sqrt{N_Q} \), a golden biquaternion is also in the form as

\[ Q = \frac{1}{2} + \frac{\sqrt{5}}{2} \overrightarrow{S_0}, \quad \langle \overrightarrow{S_0}, \overrightarrow{S_0} \rangle = 1, \quad \overrightarrow{S_0}^2 = -1. \]  \tag{8}

Now, let us see the matrix form of the golden biquaternion. Let \( Q \) be a biquaternion, i.e., \( Q = z_0 + z_1e_1 + z_2e_2 + z_3e_3 \), where \( z_j \in \mathbb{C}, \ j = 0, 1, 2, 3 \). The matrix form of \( Q \) is given by

\[
\begin{pmatrix}
  z_0 + iz_1 & z_2 + iz_3 \\
  -z_2 + iz_3 & z_0 - iz_1
\end{pmatrix}.
\]

Hence, the matrix form of the golden biquaternion \( Q = \frac{1}{2} + \frac{\sqrt{5}}{2} \overrightarrow{S_0} \), where \( \overrightarrow{S_0} = (s_1, s_2, s_3) \), is also given by

\[
\begin{pmatrix}
  \frac{1}{2} - \frac{\sqrt{5}}{2}s_1 & \frac{\sqrt{5}}{2}s_2 - \frac{\sqrt{5}}{2}s_3 \\
  -\frac{\sqrt{5}}{2}s_2 - \frac{\sqrt{5}}{2}s_3 & \frac{1}{2} + \frac{\sqrt{5}}{2}s_1
\end{pmatrix}.
\]

Now we consider the golden analogues of the examples of biquaternions given in [4].

Let’s transform the variables using the transformation

\[ T(z_1, z_2, z_3) = (iyz, izx, ixy) \]
where \( i = \sqrt{-1} \) is the imaginary number of complex algebra and \( x, y, z \in \mathbb{R} \). Under this transformation, we get

\[
z_1^2 + z_2^2 + z_3^2 = -y^2 z^2 - z^2 x^2 - x^2 y^2 = -\frac{5}{4}.
\]

(9)

There is a surface known as Steiner’s Roman Surface which has the intrinsic equation

\[
y^2 z^2 + z^2 x^2 + x^2 y^2 - r^2xyz = 0.
\]

(10)

Then, \( Q \) is a golden biquaternion if

\[
Q = \frac{1}{2} + (iyz)e_1 + (izx)e_2 + (ixy)e_3
\]

has the property that the vector \((yz, zx, xy)\) spans a Steiner’s Roman Surface.

Using (9), we can write (10) as

\[
r^2xyz = \frac{5}{4},
\]

Furthermore, if we used the transform

\[
T(z_1, z_2, z_3) = (ix, iy, iz),
\]

we have obtain the equation

\[
x^2 + y^2 + z^2 = \frac{5}{4},
\]

which corresponds to a sphere of radius \( r = \frac{\sqrt{5}}{2} \).

If we use the transforms

\[
T(z_1, z_2, z_3) = (ix, y, z),
T(z_1, z_2, z_3) = (ix, iy, z),
T(z_1, z_2, z_3) = (ix, y, iz),
T(z_1, z_2, z_3) = (x, iy, z),
T(z_1, z_2, z_3) = (x, iy, iz),
T(z_1, z_2, z_3) = (x, y, iz),
\]

then the solution surfaces will be hyperboloids.
4. Golden Split Quaternions

Now, we investigate the golden split quaternion, i.e., we try to obtain the split quaternions $Q$ that satisfy $Q^2 = Q + 1$. Let $Q = S_Q + \overrightarrow{V}_Q$. Then we have

$$Q^2 = QQ = S_Q^2 + g(\overrightarrow{V}_Q, \overrightarrow{V}_Q) + 2S_Q\overrightarrow{V}_Q.$$ 

Thus, the equation $Q^2 - Q = 1$ is equivalent to

$$S_Q^2 + g(\overrightarrow{V}_Q, \overrightarrow{V}_Q) + 2S_Q\overrightarrow{V}_Q - S_Q - \overrightarrow{V}_Q = 1,$$

and we get

$$\begin{cases} S_Q^2 + g(\overrightarrow{V}_Q, \overrightarrow{V}_Q) - S_Q = 1 \\ 2S_Q\overrightarrow{V}_Q - \overrightarrow{V}_Q = 0. \end{cases} \quad (11)$$

Thus, we have

$$S_Q = \frac{1}{2} \quad \text{or} \quad \overrightarrow{V}_Q = 0.$$ 

Therefore, there are exactly two cases for the golden split quaternions:

i) $\overrightarrow{V}_Q = 0 \Rightarrow Q = \frac{1 \pm \sqrt{5}}{2}$, 

ii) $\overrightarrow{V}_Q \neq 0 \Rightarrow S_Q = \frac{1}{2}$ and $g(\overrightarrow{V}_Q, \overrightarrow{V}_Q) = \frac{5}{4}$. \quad (12)

Hence, we can have the golden split, golden dual split or golden hyperbolic split quaternions. Now, let us try to explain these golden split quaternions, respectively. If we have a golden split quaternion with $\overrightarrow{V}_Q \neq 0$, then according to (12) we get

$$S_Q = \frac{1}{2} \quad \text{and} \quad g(\overrightarrow{V}_Q, \overrightarrow{V}_Q) = \frac{5}{4}.$$ 

Now, let $Q$ be a golden split quaternion, namely, $Q = q_0 + q_1e_1 + q_2e_2 + q_3e_3$, where $q_j \in \mathbb{R}$, $j = 0, 1, 2, 3$. Hence we get

$$q_0 = \frac{1}{2} \quad \text{and} \quad -q_1^2 + q_2^2 + q_3^2 = \frac{5}{4}. \quad (13)$$

Thus we have

$$I_Q = q_0^2 + q_1^2 + q_2^2 + q_3^2 = -1,$$ 

which shows that the golden split quaternion $Q$ is a spacelike quaternion. From [14], we know that every spacelike quaternion can be written in the form

$$Q = N_Q(\sinh \theta + \overrightarrow{S}_0 \cosh \theta),$$ \quad (15)
where \( \sinh \theta = \frac{q_1}{N} \), \( \cosh \theta = \frac{\sqrt{-q_1^2 + q_2^2 + q_3^2}}{N} \) and \( \vec{S}_0 = \frac{q_1 e_1 + q_2 e_2 + q_3 e_3}{\sqrt{-q_1^2 + q_2^2 + q_3^2}} \) is a spacelike unit vector in \( E_3^3 \). Then, according to (13), (14) and (15), a golden split quaternion is in the form

\[
Q = \frac{1}{2} + \frac{\vec{S}_0 \sqrt{5}}{2}, \quad g(\vec{S}_0, \overrightarrow{S_0}) = 1, \quad \vec{S}_0^2 = 1.
\]

Now, we present some examples related to golden split quaternions. Let’s transform the variables using the transformation

\[
T(q_1, q_2, q_3) = (yz, zx, xy)
\]

where \( x, y, z \in \mathbb{R} \). Under this transformation, we have

\[
-q_1^2 + q_2^2 + q_3^2 = -y^2 z^2 + z^2 x^2 + x^2 y^2 = \frac{5}{4}.
\]  \hspace{1cm} (16)

Besides the image of a Lorentz sphere of radius \( r \) centered at the origin under the projection

\[
(x, y, z) \mapsto (yz, zx, xy)
\]

is

\[
-y^2 z^2 + z^2 x^2 + x^2 y^2 - r^2 xyz = 0.
\]  \hspace{1cm} (17)

This surface corresponds to the Steiner’s Roman surface in the Lorentz space.

Then, \( Q \) is a golden split quaternion if

\[
Q = \frac{1}{2} + (yz)e_1 + (zx)e_2 + (xy)e_3
\]

has the property that the vector \((x, y, z)\) spans the surface in (16).

Using equation (16), we can write equation (17). as

\[
r^2 xyz = \frac{5}{4},
\]

Furthermore, if we used the transform

\[
T(q_1, q_2, q_3) = (x, y, z),
\]

then we would obtain the equality

\[
-x^2 + y^2 + z^2 = \frac{5}{4},
\]

which corresponds to a Lorentz sphere of radius \( r = \frac{\sqrt{5}}{2} \).
4.1. Golden Dual Split Quaternions

Now, we investigate the golden dual split quaternion. Let \( Q = S_Q + \overrightarrow{V_Q} \). If we have a golden split quaternion with \( \overrightarrow{V_Q} \neq 0 \), then according to (12), we have

\[
S_Q = \frac{1}{2} \quad \text{and} \quad g(\overrightarrow{V_Q}, \overrightarrow{V_Q}) = \frac{5}{4},
\]

where \( Q = Q_0 + Q_1 e_1 + Q_2 e_2 + Q_3 e_3 \) and \( Q_j = q_j + \varepsilon q_j^* \in \mathbb{D}, j = 0, 1, 2, 3 \). Then we have

\[
Q_0 = \frac{1}{2} \quad \text{and} \quad -Q_1^2 + Q_2^2 + Q_3^2 = \frac{5}{4}.
\]

Thus we have

\[
-q_1^2 + q_2^2 + q_3^2 = \frac{5}{4} \quad \text{and} \quad -q_1 q_1^* + q_2 q_2^* + q_3 q_3^* = 0,
\]

which implies that

\[
I_Q = Q_0^2 + Q_1^2 - Q_2^2 - Q_3^2 = -1.
\]

Hence we can write

\[
Q = N_Q(\sinh \theta + S_0 \cosh \theta),
\]
where \( \sinh \theta = \frac{q_1}{N q_1} \), \( \cosh \theta = \sqrt{-q_1^2 + q_2^2 + q_3^2} \) and \( \vec{S}_0 = \frac{q_1 e_1 + q_2 e_2 + q_3 e_3}{\sqrt{-q_1^2 + q_2^2 + q_3^2}} \) is a space-like unit dual vector in \( E_3^1 \). Then, according to (18), (19) and (20), a golden split quaternion is in the form

\[
Q = \frac{1}{2} \sqrt{\frac{5}{2}}, \quad g(\vec{S}_0, \vec{S}_0^\top) = 1, \quad \vec{S}_0^2 = 1.
\]

Now, we present some examples related to golden dual split quaternions. Let us transform the variables using

\[
T(Q_1, Q_2, Q_3) = (\varepsilon yz, \varepsilon zx, \varepsilon xy)
\]

where \( \varepsilon \) is the imaginary number of the algebra of dual numbers and \( x, y, z \in \mathbb{R} \). Under this transformation, we have

\[-Q_1^2 + Q_2^2 + Q_3^2 = 0.\]

Hence, we can’t use pure dual numbers in \( Q_1, Q_2, Q_3 \).

If we use the transforms

\[
T(Q_1, Q_2, Q_3) = (\varepsilon x, y, z),
\]

\[
T(Q_1, Q_2, Q_3) = (\varepsilon x, \varepsilon y, z),
\]

\[
T(Q_1, Q_2, Q_3) = (\varepsilon x, y, \varepsilon z),
\]

\[
T(Q_1, Q_2, Q_3) = (x, \varepsilon y, z),
\]

\[
T(Q_1, Q_2, Q_3) = (x, \varepsilon y, \varepsilon z),
\]

\[
T(Q_1, Q_2, Q_3) = (x, y, \varepsilon z),
\]

then the solution surfaces will be cylinders and planes as given below:

\[
\begin{align*}
y^2 + z^2 &= \frac{5}{4}, \\
z^2 &= \frac{5}{4}, \\
y^2 &= \frac{5}{4}, \\
x^2 + z^2 &= \frac{5}{4}, \\
x^2 &= \frac{5}{4}, \\
x^2 + y^2 &= \frac{5}{4}.
\end{align*}
\]
4.2. Golden Hyperbolic Split Quaternions

Finally, we investigate the golden hyperbolic split quaternion. Let \( Q = S_Q + \vec{V}_Q \). If we have a golden split quaternion with \( \vec{V}_Q \neq 0 \), then according to (12), we have

\[
S_Q = \frac{1}{2} \quad \text{and} \quad g(\vec{V}_Q, \vec{V}_Q) = \frac{5}{4},
\]

where \( Q = Q_0 + Q_1e_1 + Q_2e_2 + Q_3e_3 \) and \( Q_j = q_i + jq_i' \in \mathbb{H}, i = 0, 1, 2, 3 \). Then we have

\[
Q_0 = \frac{1}{2} \quad \text{and} \quad - Q_1^2 + Q_2^2 + Q_3^2 = \frac{5}{4}.
\]

Thus we obtain

\[
-q_1^2 + q_2^2 + q_3^2 - q_1'^2 + q_2'^2 + q_3'^2 = \frac{5}{4} \quad \text{and} \quad -q_1q_1' + q_2q_2' + q_3q_3' = 0,
\]

which implies that

\[
I_Q = Q_0^2 + Q_1^2 - Q_2^2 - Q_3^2 = -1.
\]

Since \( I_Q = -1 \), we can write

\[
Q = N_Q(\sinh \theta + \vec{S}_0 \cosh \theta),
\]

where \( \sinh \theta = \frac{Q_0}{N_Q} \), \( \cosh \theta = \frac{\sqrt{-Q_1^2 + Q_2^2 + Q_3^2}}{N_Q} \) and \( \vec{S}_0 = \frac{Q_1e_1 + Q_2e_2 + Q_3e_3}{\sqrt{-Q_1^2 + Q_2^2 + Q_3^2}} \) is a spacelike unit hyperbolic vector in \( \mathbb{E}_3^1 \). Then, according to (21), (22) and (23), a golden split quaternion is in the form

\[
Q = \frac{1}{2} + \frac{\sqrt{5}}{2} \vec{S}_0, \quad g(\vec{S}_0, \vec{S}_0) = 1, \quad \vec{S}_0^2 = 1.
\]

Now, we give some examples for golden hyperbolic split quaternions. Let us transform the variables using the transformation

\[
T(Q_1, Q_2, Q_3) = (jyz, jzx, jxy)
\]

where \( j^2 = 1 \) is the imaginary number of the hyperbolic algebra and \( x, y, z \in \mathbb{R} \). Under this transformation, we get

\[
-Q_1^2 + Q_2^2 + Q_3^2 = -y^2z^2 + z^2x^2 + x^2y^2 = \frac{5}{4}.
\]

Then, \( Q \) is a golden hyperbolic split quaternion if

\[
Q = \frac{1}{2} + (jyz)e_1 + (jzx)e_2 + (jxy)e_3
\]
has the property that the vector \((x, y, z)\) span the Surface in (17).

Furthermore, if we use the transform

\[
T(Q_1, Q_2, Q_3) = (jx, jy, jz),
\]
then we obtain the equation

\[
-x^2 + y^2 + z^2 = \frac{5}{4},
\]

which corresponds to a Lorentz sphere of radius \(r = \sqrt{\frac{5}{4}}\).

Finally, if we use the transforms

\[
T(Q_1, Q_2, Q_3) = (jx, y, z),
T(Q_1, Q_2, Q_3) = (jx, jy, z),
T(Q_1, Q_2, Q_3) = (jx, y, jz),
T(Q_1, Q_2, Q_3) = (x, jy, z),
T(Q_1, Q_2, Q_3) = (x, jy, jz),
T(Q_1, Q_2, Q_3) = (x, y, jz),
\]
then the solution surfaces will be exactly a Lorentz sphere of radius \(r = \sqrt{\frac{5}{4}}\).
